12/2021

Rotary encoders from HEIDENHAIN serve as feedback devices for rotary motion and angular speed. When used in conjunction with mechanical measuring standards such as lead screws, they can also measure linear motion. Possible applications include electric motors, machine tools, printing machines, woodworking machines, textile machines, robots, and handling devices, as well as a wide variety of measuring, testing, and inspection devices. The high quality of their sinusoidal incremental signals permits high interpolation factors for digital speed control.

Rotary encoders with mounted stator coupling

Information about

- Encoders for servo drives
- Sealed angle encoders
- Modular angle encoders with optical scanning
- Modular angle encoders with magnetic scanning
- Linear encoders for numerically controlled machine tools
- Exposed linear encoders
- Signal converters
- HEIDENHAIN controls, and
- Cables and connecting elements is available upon request as well as on the Internet at www.heidenhain.com.

Further information:

For detailed descriptions of all available interfaces, as well as general electrical information, please refer to the *Interfaces of HEIDENHAIN Encoders* brochure.

This brochure supersedes all previous editions, which thereby become invalid. The basis for ordering from HEIDENHAIN is always the current product documentation at the time the order is placed.

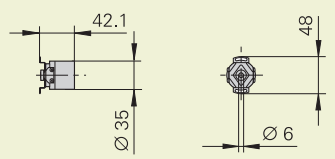

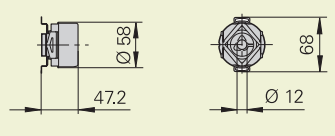

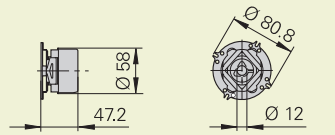

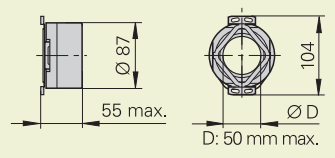

Standards (ISO, EN, etc.) apply only where explicitly stated in this brochure.

Measuring principles

Measuring standards

HEIDENHAIN encoders with **optical scanning** use measuring standards consisting of periodic structures known as graduations. These precision graduations are applied to a carrier substrate made of glass or steel and are manufactured by means of various photolithographic processes. Graduations are made from the following materials:

- Extremely hard chromium lines on glass
- Matte-etched lines on gold-plated steel tape
- Three-dimensional structures on glass or steel substrates

The photolithographic manufacturing processes developed by HEIDENHAIN allow for typical grating periods ranging from 50 µm down to 4 µm.

These processes yield fine grating periods characterized by excellent edge definition and high homogeneity. In combination with the photoelectric scanning method, these characteristics are crucial for attaining high-quality output signals.

The master graduations are manufactured by HEIDENHAIN on custom-built, high-precision dividing engines.

Encoders that use the **inductive scanning principle** employ metal graduations or copper/nickel-based graduation structures. These graduation structures are applied to a printed-circuit carrier material.

Measuring methods

In the **absolute measuring method**, the position value is available immediately upon encoder switch-on and can be requested by the downstream electronics at any time. There is therefore no need to search for the reference position by jogging the axes. The resulting absolute position information **is read from the circular scale**, which exhibits a code structure.

Circular scales of absolute rotary encoders

In the **incremental measuring method**, the graduation consists of a periodic grating structure. Position information is obtained **through the counting** of individual increments (measuring steps) starting from a freely settable point of origin. Since position ascertainment requires an absolute reference, the circular scales have an additional track containing a **reference mark**.

Circular scales of incremental rotary encoders

A separate incremental track is interpolated for the position value and is simultaneously used for generating an optional incremental signal.

Singletum rotary encoders repeat the absolute position information with each revolution. **Multitum encoders** can distinguish between additional revolutions.

The absolute position established by the reference mark is assigned to exactly one measuring step.

Thus, before an absolute reference can be established or the most recently selected reference point can be refound, this reference mark must first be traversed.

Scanning methods

Photoelectric scanning

Most HEIDENHAIN encoders utilize the photoelectric scanning principle. Photoelectric scanning is performed contact-free and thus does not induce wear. This method detects even extremely fine graduation lines down to a width of only a few micrometers and generates output signals with very small signal periods.

The ECN, EQN, ERN, ROC, ROQ, and ROD rotary encoders utilize the imaging scanning principle.

Put simply, the imaging scanning principle uses projected-light signal generation; for example, two gratings (a scale and a scanning reticle) with the same grating period are moved relative to each other. The carrier material of the scanning reticle is transparent. The graduation on the measuring standard can be applied to either a transparent surface or a reflective surface.

When parallel light passes through a grating structure, light and dark fields are projected at a certain interval. At the place where these fields are projected lies an index grating with the same grating period. When these two graduations move relative to each other, the incident light is modulated: If the gaps are aligned, light passes through. If the lines of one grating coincide with the gaps of the other, no light passes through. Photocells convert these light fluctuations into nearly sinusoidal electrical signals. In encoders that use the imaging scanning principle, workable mounting tolerances are attainable starting at a minimum grating period of 10 µm.

Photoelectric scanning according to the imaging scanning principle

The absolute rotary encoders that use this scanning principle have a single, large, and finely structured photosensor as opposed to a group of discrete photocells. The width of the photosensor's structures is identical to the width of the measuring standard's grating structure. A scanning reticle with a matching structure is therefore not needed.

Other scanning principles

The ECI/EBI/EQI rotary encoders utilize the inductive measuring principle. In this case, the graduation structures modulate the amplitude and phase of a high-frequency signal. By means of circumferential scanning, the position value is always generated based on the signals from the receiver coils that are evenly distributed along the circumference.

Rotary encoder accuracy is primarily determined by the following factors:

- The directional error of the radial grating
- The eccentricity of the circular scale relative to the bearing
- The radial runout of the bearing
- The error arising from connection via a shaft coupling; for rotary encoders with stator coupling, this error lies within the system accuracy
- The interpolation error that arises during signal processing in the integrated or external digitizing and interpolation electronics

The following applies to **incremental rotary encoders** with line counts of up to 5000: The maximum direction error at 20 °C ambient temperature and slow rotation (sampling frequency between 1 kHz and 2 kHz) is within

$$\pm \frac{18^\circ \text{ mech.} \cdot 3600}{\text{Line count } z} \text{ [arc seconds]}$$

which equals

$$\pm \frac{1}{20} \text{ grating period.}$$

In the case of ROD rotary encoders, the 6000 to 10 000 signal periods per revolution are generated via signal doubling. The line count must be considered in determining the system accuracy.

For **absolute rotary encoders**, the accuracy of the absolute position values is provided in the specifications of the respective encoder.

For absolute rotary encoders with **complementary incremental signals**, the accuracy depends on the line count:

Line count	Accuracy
512	±60 arc seconds
2048	±20 arc seconds
2048	±10 arc seconds (ROC 425 with high accuracy)

This accuracy information applies to incremental measurement signals at 20 °C ambient temperature and slow rotation.

Mechanical design types and mounting

Rotary encoders with stator coupling

The **ECN/EQN/ERN** rotary encoders feature integrated bearings and a mounted stator coupling. The stator coupling compensates for radial runout and alignment errors without significantly reducing the accuracy. The rotary encoder shaft is directly connected to the measured shaft. During angular acceleration of the shaft, the stator coupling must absorb only the torque resulting from friction within the bearing. The stator coupling permits a certain amount of axial motion in the measured shaft:

ECN/EQN/ERN 400: ±1 mm

ECN/EQN/ERN 1000: ±0.5 mm

ECN/ERN 100: ±1.5 mm

Mounting

The hollow shaft of the rotary encoder is slid onto the measured shaft and fastened on the rotor side by two screws or three eccentric clamps. Rotary encoders with a hollow through shaft can be clamped on the housing side as well. Particularly well suited for repeated mounting are the ECN/EQN/ERN 1300 series rotary encoders featuring a tapered shaft (see the *Encoders for Servo Drives* brochure). Stator-side mounting is performed on a plane surface without a centering collar. The **universal stator coupling** of the ECN/EQN/ERN 400 accommodates a variety of mounting scenarios; for example, it can be mounted to the motor housing from the outside via the provided threads.

Mechanical fault exclusion is possible for the ECN/EQN/ERN 400 series rotary encoders featuring a standard stator coupling and blind hollow shaft.

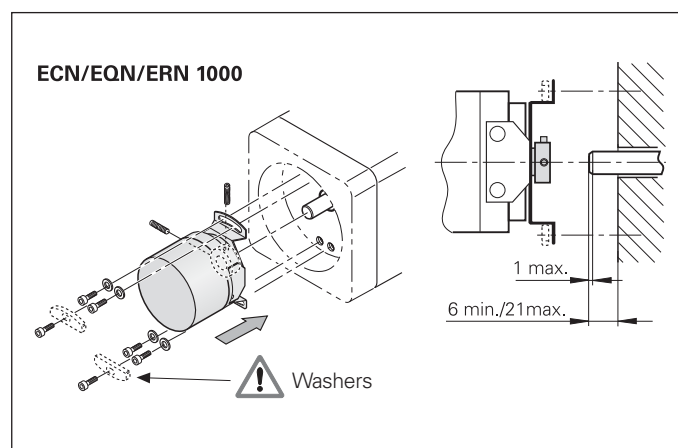

Dynamic applications require the highest possible natural frequencies f_N of the system's coupling (see also General mechanical information). These natural frequencies can be attained through the shaft clamping on the flange side and a coupling with four screws. The ECN/EQN/ERN 1000 encoders offer an alternative with two screws and two washers.

Typical natural frequency f_N of the connection with stator-side coupling via four screws:

	Stator coupling	Cable	Flange socket	
			Axial	Radial
ECN/EQN/ERN 400	Standard	1550 Hz	1500 Hz	1000 Hz
	Universal	1400 Hz ¹⁾	1400 Hz	900 Hz
ECN/ERN 100		1000 Hz	–	400 Hz
ECN/EQN/ERN 1000		1500 Hz ²⁾	–	–

¹⁾ Also with fastening via two screws

²⁾ Also with fastening via two screws and washers

Mounting accessories

Clamping ring

For the ECN/EQN/ERN 400
Through the use of a second clamping ring, the maximum mechanically permissible shaft speed of rotary encoders with a hollow through shaft can be increased up to 12000 rpm.
ID 540741-xx

In the case of safe, hollow-shaft connections, repeated fastening reduces the screw force. In order to maintain the required safety factor for friction-type connections, the maximum number of permissible screw tightening repetitions is limited to four. Beyond this number of repetitions, mechanical fault exclusion cannot be guaranteed. In such cases, new clamping rings must be ordered separately.

Clamping ring for 10 mm ID 540741-06
Clamping ring for 12 mm ID 540741-07

When **high shaft loads** are involved, such as with friction wheels, pulleys, or sprockets, HEIDENHAIN recommends mounting the ECN/EQN/ERN 400 with a bearing assembly.

Bearing assembly

For the ECN/EQN/ERN 400 with blind hollow shaft
ID 574185-03

The bearing assembly is able to absorb large radial shaft loads and prevents overloading of the encoder bearing. On the encoder side, the bearing assembly features a shaft stub with a diameter of 12 mm, thus making it suitable for the ECN/EQN/ERN 400 encoders featuring a blind hollow shaft. The threaded holes for fastening the stator coupling are also already provided. The flange of the bearing assembly has the same dimensions as those of the clamping flange for the ROD 420/430 series. The bearing assembly can be fastened via the threaded holes on its front face or with the aid of the mounting flange or the mounting bracket (see page 21 for both).

	Bearing assembly
Permiss. shaft speed n	≤ 6000 rpm
Shaft load	Axial: 150 N; radial: 350 N
Operating temperature	–40 °C to 100 °C
Protection EN 60529	IP64

Mounting accessories

Washer

For the ECN/EQN/ERN 1000
For increasing the natural frequency f_N
when fastening with only two screws
ID 334653-01

Torque supports for the ECN/EQN/ERN 400

In simpler applications with the ECN/EQN/ERN 400, the stator coupling can be replaced by torque supports. The following mounting kits are available:

Wire torque support

The stator coupling is replaced by a metal plate to which the included wire is fastened as a coupling.
ID 510955-01

Pin torque support

In place of a stator coupling, a "synchro flange" is fastened via screws. Torque support is provided by a pin mounted axially or radially on the flange. Alternatively, the pin can be inserted on the customer side, and a guide on the encoder's flange is then used for the pin coupling.
ID 510861-01

General accessories

Rotary encoders for separate shaft coupling

The **ROC/ROQ/ROD** rotary encoders feature an integral bearing and a solid shaft. The encoder shaft is connected to the measured shaft with a separate shaft coupling. This coupling compensates for axial movement and misalignment (radial and angular misalignment) between the rotary encoder and the drive shaft. Thus, the encoder bearing is not subjected to additional external loads, and its service life remains unaffected. Diaphragm and metal bellows couplings are available for rotor-side connection of the ROC/ROQ/ROD encoders (see page 24).

The ROC/ROQ/ROD 400 and ROD 600 series rotary encoders permit high bearing loads (see diagrams). When high loads are involved, such as with friction wheels, pulleys, or sprockets, HEIDENHAIN recommends using an ECN/EQN/ERN 400 mounted to a bearing assembly. For very high bearing loads, the ROD 1930 is a suitable choice.

The shafts to be connected must be mounted with minimum relative offset to each other. For typical mounting tolerances, refer to the "Kinematic transfer error" on page 24.

Bearing service life of the ROC/ROQ/ROD 400

The expected service life of the encoder bearing depends on the shaft load, the point of applied force, and the shaft speed. The *Specifications* provide the maximum shaft loads permitted at the end of the shaft. The relationship between the bearing service life and shaft speed under maximum shaft load for 6 mm and 10 mm shaft diameters is shown in the upper diagram. Under an axial load of 10 N and a radial load of 20 N at the shaft end, the expected bearing service life at maximum shaft speed is greater than 40000 hours.

Bearing life of the ROD 600

Rotary encoders of the ROD 600 series are designed for a long service life under high bearing loads.

Bearing service life of the ROD 1930

The ROD 1930 is designed for a long service life under very high bearing loads.

Rotary encoders with synchro flange

Mounting

- Via the synchro flange with three fixing clamps, or
- To an adapter flange via the fastening screw threads on the front face (for ROC/ROQ/ROD 400)

Mechanical fault exclusion is possible upon consultation with HEIDENHAIN in Traunreut, Germany.

Rotary encoders with clamping flange

Mounting

- To a mounting flange via the fastening threads on the front face, or
- Via clamping on the clamping flange, or
- With three fixing clamps (for encoders with an additional groove on the clamping flange)

Centering is performed via the centering collar on the synchro flange or via the clamping flange.

Mechanical fault exclusion is possible upon consultation with HEIDENHAIN in Traunreut, Germany.

Rotary encoder with flange/base mounting

Mounting

- Via mounting flange, or
 - Via base
- Fastening is performed with four M8 screws.

The terminal box can be mounted at any 90° orientation.

Shaft coupling

For optimum torque transmission, the encoder shaft is equipped with a key. The C19 and C 212 couplings, which are available as accessories, feature a matching keyway.

Certification by NRTL (Nationally Recognized Testing Laboratory)

All of the rotary encoders in this brochure comply with the UL safety regulations for the U.S. and with the CSA safety regulations for Canada.

Accelerations

During mounting and operation, encoders are subjected to various types of acceleration.

• Vibration

The encoders are qualified on a test stand under the acceleration values stated in the specifications at frequencies of 55 Hz to 2000 Hz in accordance with EN 60068-2-6. However, if the application or mounting situation causes long-duration resonant vibration, then proper functioning of the encoder may be impaired, or the encoder itself may incur damage.

Thorough testing of the complete system is therefore required.

• Shock

The encoders are qualified on a test stand under the acceleration values stated in the specifications and under the exposure times in accordance with EN 60068-2-27 for non-repetitive, semi-sinusoidal shock. **Continuous shock loads** are therefore not covered and **must be tested in the application.**

- The **maximum angular acceleration** is 10^5 rad/s^2 . This is the maximum permissible angular acceleration of the rotor without the encoder incurring damage. The actual attainable angular acceleration is within the same order of magnitude but can vary depending on the type of shaft connection (for deviating values for the ECN/ERN 100, see the *Specifications*). An adequate safety factor must be determined through system tests.

Deviating values for rotary encoders with functional safety are provided in the corresponding Product Information documents.

Humidity

The maximum permissible relative humidity is 75 %. A relative humidity of 93 % is temporarily permissible. Condensation is not permissible.

Magnetic fields

Magnetic fields > 30 mT can affect encoder functioning. Please contact HEIDENHAIN in Traunreut, Germany, as needed.

Natural frequencies

With the ROC/ROQ/ROD rotary encoders, the rotor and the shaft coupling together form an oscillation-capable spring-mass system. In the case of the ECN/EQN/ERN, this applies to the stator and stator coupling.

The **natural frequency f_N** should be as high as possible. In order for the highest possible natural frequency to be attained with the **ROC/ROQ/ROD rotary encoders**, a diaphragm coupling with a high torsional rigidity C must be used (see *Shaft couplings*).

$$f_N = \frac{1}{2 \times \pi} \cdot \sqrt{\frac{C}{I}}$$

f_N : Natural frequency of the coupling in Hz
C: Torsional rigidity of the coupling in Nm/rad
I: Moment of inertia of the rotor in kgm^2

In conjunction with the stator coupling, the **ECN/EQN/ERN** rotary encoders form an oscillation-capable spring-mass system whose **natural frequency f_N** of the coupling in the direction of measurement should be as high as possible. The natural frequency of the coupling is influenced by the rigidity of the stator coupling and by the customer-side mounting situation. The stated typical natural frequencies may vary depending on the encoder variant (e.g., singleturn or multiturn), production tolerances, and differing mounting conditions. If radial and/or axial acceleration forces also come into play, then the rigidity of the encoder bearing and of the encoder stator has an effect as well. If such loads occur within your application, HEIDENHAIN recommends consulting with the main facility in Traunreut.

HEIDENHAIN generally recommends determining the natural frequency of the stator coupling in the complete system.

Starting torque and operating torque

The starting torque is the torque required to put the rotor into motion from standstill. If the rotor is already rotating, then a certain operating torque is acting on the encoder. The starting torque and operating torque are influenced by various factors, such as the temperature, prior standstill time, and the amount of wear on the bearings and seals.

The typical values stated in the specifications are mean values based on encoder-specific test series performed at room temperature and at a stabilized operating temperature. The typical operating torques are also based on constant shaft speeds. For applications in which the torque has a significant influence, HEIDENHAIN recommends consulting with the main facility in Traunreut.

Protection against contact (EN 60529)

After completed installation of the encoder, any rotating parts must be sufficiently protected from unintentional contact during operation.

Protection (EN 60529)

The ingress of contamination can impair proper functioning of the encoder. Unless otherwise indicated, all of the rotary encoders have an IP64 rating (ExN/ROx 400: IP67) in accordance with EN 60529. These specifications apply to the housing, cable outlet, and flange socket versions when engaged.

The **shaft inlet** meets an IP64 rating. Splash water must not be allowed to have any harmful effect on the encoder's parts. If the protection rating of the shaft inlet is not sufficient (e.g., due to vertical mounting of the encoder), then the encoders should be additionally protected with labyrinth seals. Many encoders are also available with an IP66 rating for the shaft inlet. Depending on the application, the radial shaft seal rings used for sealing are subjected to wear due to friction.

Noise emission

Running noise can occur during operation. This is particularly true of encoders with integral bearing and multiturn rotary encoders (with gears). The intensity may vary depending on the mounting situation and shaft speed.

System tests

Encoders from HEIDENHAIN are usually integrated as components into complete systems. Such applications require **comprehensive testing of the complete system**, irrespective of the encoder's specifications.

The specifications provided in this brochure apply only to the encoder and not to the complete system. Any operation of the encoder outside of the specified range or outside of its proper and intended use is solely at the user's own risk.

Mounting

The steps and dimensions that must be complied with during mounting are specified solely in the mounting instructions supplied with the device. All mounting-related information in this brochure is therefore only provisional and non-binding, and will not become the subject matter of a contract.

All provided information on screw connections assumes a mounting temperature of 15 °C to 35 °C.

Screws with material bonding anti-rotation lock

Mounting screws and central screws from HEIDENHAIN (not included in delivery) feature a coating that, after hardening, provides a material bonding anti-rotation lock. As a result, these screws cannot be reused. Their minimum shelf life is two years (storage at ≤ 30 °C and ≤ 65 % relative humidity). Their expiration date is printed on the package.

Screw insertion and the application of tightening torque must therefore be completed within five minutes. The required strength is reached at room temperature after six hours. The lower the temperature, the longer the curing process will take. Curing temperatures below 5 °C are not permissible.

Screws with material bonding anti-rotation lock must not be used more than once. If a replacement becomes necessary, recut the threads and use new screws. On threaded holes, a chamfer is required in order to keep the adhesive coating from being scraped off.

For the fault exclusion design for functional safety, the following material properties and conditions for the mating surfaces are assumed.

	Aluminum	Steel
Material type	Hardenable wrought aluminum alloys	Unalloyed hardened steel
Tensile strength R_m	≥ 220 N/mm ²	≥ 600 N/mm ²
Yield strength $R_{p0.2}$ or yield point R_e	Not applicable	≥ 400 N/mm ²
Shear strength τ_a	≥ 130 N/mm ²	≥ 390 N/mm ²
Interface pressure p_G	≥ 250 N/mm ²	≥ 660 N/mm ²
Elastic modulus E (at 20 °C)	70 kN/mm ² to 75 kN/mm ²	200 kN/mm ² to 215 kN/mm ²
Coefficient of thermal expansion α_{therm} (at 20 °C)	≤ 25 · 10 ⁻⁶ K ⁻¹	10 · 10 ⁻⁶ K ⁻¹ to 17 · 10 ⁻⁶ K ⁻¹
Surface roughness Rz	≤ 16 μm	
Friction values	Mounting surfaces must be clean and free of grease. Use screws and washers in their condition as delivered.	
Tightening procedure	Use a signal-emitting torque wrench in accordance with DIN EN ISO 6789, with an accuracy of ±6 %	
Mounting temperature	15 °C to 35 °C	

Rotary encoders can exert a torque of 1 Nm on the mating shaft. The mating mechanics must be designed for this load. If further requirements must be complied with, then these are provided in the respective Product Information document.

Modifications to the encoder

The proper functioning and accuracy of encoders from HEIDENHAIN are ensured only if the encoders have not been modified. Any modification, even a minor one, can impair the proper functioning, reliability, and safety of the encoders, and result in a loss of warranty. This also includes the use of any additional or non-prescribed locking varnishes, lubricants (e.g., for screws), or adhesives. If you are in doubt, we recommend that you consult with HEIDENHAIN in Traunreut, Germany.

Conditions for longer storage times

For a storage period of twelve months or longer, HEIDENHAIN recommends the following:

- Leave the encoders in their original packaging
- The storage location should be dry, free of dust, and temperature-regulated. It should also be free of vibration, mechanical shock, and chemical environmental influences
- Every twelve months, rotate the shafts of the encoders with integral bearing at low speed and without axial or radial shaft loading so that the bearing lubrication becomes evenly redistributed (e.g., such as when first breaking in an encoder)

Parts subject to wear

Encoders from HEIDENHAIN are designed for a long service life. Preventive maintenance is not required. However, they do contain components that are subject to wear, depending on the application and how they are deployed. This especially applies to cables that are subjected to frequent flexing. Other parts subject to wear are the bearings in encoders with integral bearing, the radial shaft seal rings in rotary encoders and angle encoders, and the sealing lips on linear encoders.

In order to avoid damage from current flows, some rotary encoders are available with hybrid bearings. In general, these bearings exhibit greater wear at high temperatures than standard bearings.

Service life

Unless otherwise specified, HEIDENHAIN encoders are designed for a service life of 20 years, which is equivalent to 40000 operating hours under typical operating conditions.

Temperature ranges

For encoders still in their packaging, a **storage temperature range** of -30 °C to 65 °C applies (HR 1120: -30 °C to 70 °C).

The **operating temperature range** specifies the temperatures that a rotary encoder is permitted to reach during operation in the actual installation environment. Within this range, proper functioning of the rotary encoder is ensured. The operating temperature is measured at the defined measuring point (see dimension drawing) and must not be confused with the ambient temperature.

The temperature of the rotary encoder is influenced by the following factors:

- The mounting conditions
- The ambient temperature
- The encoder's susceptibility to self-heating

An encoder's susceptibility to self-heating depends both on its design characteristics (stator coupling / solid shaft, shaft sealing ring, etc.) and on its operating parameters (shaft speed, supply voltage). A temporary period of heightened self-heating can also occur after very long breaks in operation (of several months). Please allow for a two-minute break-in period at low shaft speeds. The greater susceptibility to self-heating that an encoder exhibits, the lower the ambient temperature needs to be in order to keep the encoder within its permissible operating temperature range.

This table shows the approximate self-heating values to be expected for the rotary encoders. In the worst case, the amount of self-heating may be affected by multiple operating parameters, such as a 30 V supply voltage and maximum shaft speed. Thus, if an encoder is being operated close to its maximum permissible specifications, then the actual operating temperature should be measured directly at the encoder. Suitable measures must then be taken (fan, heat sinks, etc.) to sufficiently reduce the ambient temperature so that the maximum permissible operating temperature will not be exceeded during continuous operation.

For high shaft speeds at the maximum permissible ambient temperature, special versions with a reduced protection rating are available (without a radial shaft seal ring and its concomitant frictional heat).

Self-heating at shaft speed n_{max}

<i>Solid shaft / tapered shaft</i> ROC/ROQ/ROD/ ExN 400/1300	≈ +5 K ≈ +10 K with IP66 rating
ROD 600	≈ +75 K
ROD 1900	≈ +10 K
<i>Blind hollow shaft</i> ECN/EQN/ERN 400/1300	≈ +30 K ≈ +40 K with IP66 rating
ECN/EQN/ERN 1000	≈ +10 K
<i>Hollow through shaft</i> ECN/ERN 100 ECN/EQN/ERN 400	≈ +40 K with IP64 rating ≈ +50 K with IP66 rating

Typical self-heating values of a rotary encoder at maximum permissible shaft speed based on its design characteristics. The relationship between shaft speed and heat generation is nearly linear.

Measuring the actual operating temperature at the defined measuring point of the rotary encoder (see *Specifications*)

Safety-related position measuring systems

The term “functional safety” designates HEIDENHAIN encoders that are suitable for deployment in safety-related applications. These encoders operate as single-encoder systems with purely serial data transmission via the EnDat 2.2 or DRIVE-CLiQ interface. The reliable transmission of the position is based on two independently generated absolute position values and on error bits provided to the safe control.

Basic principle

HEIDENHAIN measuring systems for safety-related applications are tested for compliance in accordance with the standards EN ISO 13849-1 (successor to EN 954-1), EN 61508, and EN 61800-5-2. In these standards, the assessment of safety-related systems is based on, among other things, the failure probabilities of integrated components and subsystems. This modular approach makes it easier for the manufacturers of safety-related systems to realize their complete systems, allowing them to build upon already qualified subsystems. Safety-related position measuring systems with purely serial data transmission via EnDat 2.2 or DRIVE-CLiQ take this approach into account. In a safe drive system, the safety-related position measuring system represents such a subsystem. A **safety-related position measuring system** (e.g., with EnDat 2.2) consists of the following:

- An encoder with an EnDat 2.2 transmission component
- A data transfer line with EnDat 2.2 communication and HEIDENHAIN cable
- An EnDat 2.2 receiver component with monitoring functionality (EnDat Master)

In practice, the **complete “safe drive system”** (e.g., for EnDat 2.2) consists of the following:

- A safety-related position measuring system
- A safety-related control (including the EnDat Master with monitoring functions)
- A power stage with motor power cable and motor
- A mechanical connection between the encoder and motor (e.g., rotor/stator connection)

Area of application

Safety-related position measuring systems from HEIDENHAIN are designed to be usable as single-encoder systems in applications with control category SIL 2 (as per EN 61508), PL d, Category 3 (as per EN ISO 13849).

Additional measures in the control enable the use of certain encoders for applications with up to SIL 3, PL e, Category 4. The suitability of these encoders is indicated in the documentation (brochures and Product Information documents).

The functions of the safety-related position measuring system can be used for the following safety tasks of the complete system (see also EN 61800-5-2):

SS1	Safe Stop 1
SS2	Safe Stop 2
SOS	Safe Operating Stop
SLA	Safely Limited Acceleration
SAR	Safe Acceleration Range
SLS	Safely Limited Speed
SSR	Safe Speed Range
SLP	Safely Limited Position
SLI	Safely Limited Increment
SDI	Safe Direction
SSM	Safe Speed Monitor

Safety functions according to EN 61800-5-2

Complete safe drive system with EnDat 2.2

Principle of operation

The safety design of the position measuring system is based on two mutually independent position values generated in the encoder, and on additional error bits. With EnDat 2.2, for example, these data are transmitted to the EnDat Master via the EnDat 2.2 protocol. The EnDat Master performs various monitoring functions that help detect errors in the encoder and data transmission. For example, a comparison of the two position values is performed. The EnDat Master then makes the data available to the safe control. The control monitors the functionality of the safety-related position measuring system through periodically triggered tests.

The architecture of the EnDat 2.2 protocol enables the processing of all safety-relevant information or control mechanisms during unimpaired normal operation. This is possible because the safety-relevant information is contained within the so-called additional data. According to EN 61508, the architecture of the position measuring system is regarded as a single-channel tested system.

Integration of the position measuring system: documentation

In order for a position measuring system to be used properly, demands are placed on the control, machine designer, installation technician, servicing personnel, and others. The required information is provided in the documentation for the position measuring systems.

In order to be able to implement a position measuring system in a safety-related application, a suitable control is required. The control performs the essential tasks of carrying out communication with the encoder and reliably evaluating the encoder data.

The requirements for integrating the EnDat Master with monitoring functions into the safe control are described in HEIDENHAIN Document 533095. For example, this document contains requirements pertaining to the electrical connection, cyclic tests of the position measuring system, and the evaluation and further processing of position values. Supplementing this, Document 1000344 describes measures that enable the use of suitable encoders in applications with up to SIL 3, PL e, Category 4.

Machine and equipment manufacturers need not attend to these details themselves. This functionality must be provided by the control. Product information documents, brochures, and mounting instructions provide information to aid in the selection of a suitable encoder. The **Product Information document** and **brochure** contain general information on the functionality and application of the encoders, as well as specifications and permissible ambient conditions. The **mounting instructions** provide detailed information about installing the encoders.

The architecture of the safety system and the diagnostic capabilities of the control may define or specify further requirements.

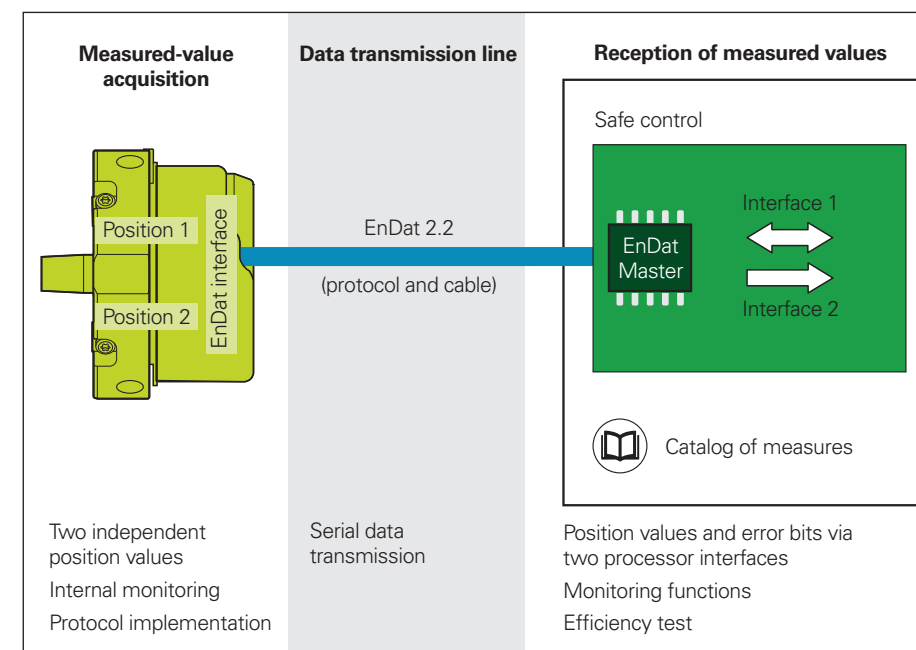

Thus, in the operating instructions for the control, it must be explicitly stated whether fault exclusion is required for the loosening of the mechanical connection between the encoder and the motor. Any resulting requirements must be relayed by the machine designer to the installation technician and the servicing staff, for example.

Fault exclusion for the loosening of the mechanical connection

Irrespective of the interface, many safety designs require a safe mechanical connection of the encoder. The standard for electric motors, EN 61800-5-2, defines the loosening or loss of the mechanical connection between the encoder and motor as a fault that requires consideration. In many cases, fault exclusion is required because the control is not necessarily capable of detecting such errors.

Standard encoders

In addition to those encoders explicitly qualified for safety applications, standard encoders (e.g., with 1 V_{PP} signals) can be used in safe applications as well. In such cases, the characteristics of the encoders must be matched to the requirements of the respective control. To this end, HEIDENHAIN can provide additional data about the individual encoders (failure rate, fault model as per EN 61800-5-2).

Safety-related position encoder with EnDat 2.2

Further information:

For more information on the topic of functional safety, please refer to the Technical Information documents *Safety-Related Position Measuring Systems* and *Safety-Related Control Technology*, as well as the Product Information documents for encoders with functional safety, and to the Customer Information documents on fault exclusion.

Interfaces

~ 1 V_{PP} incremental signals

HEIDENHAIN encoders with the ~ 1 V_{PP} interface provide voltage signals that can be highly interpolated.

The sinusoidal **incremental signals** A and B are phase-shifted by 90° elec. and have a typical amplitude of 1 V_{PP}. The illustrated sequence of output signals—with B lagging A—applies to the direction of motion shown in the dimension drawing.

The **reference mark signal** R has a unique assignment to the incremental signals. The output signal may be lower next to the reference mark.

Further information:

For detailed descriptions of all available interfaces, as well as general electrical information, please refer to the *Interfaces of HEIDENHAIN Encoders* brochure.

HEIDENHAIN offers signal converters for adapting encoders to the interface of the downstream electronics. For information about this, please refer to the *Signal Converters* Product Overview.

¹⁾ LIDA 2xx: vacant

□ TTL incremental signals

HEIDENHAIN encoders with the □ TTL interface incorporate electronics that digitize sinusoidal scanning signals with or without interpolation.

The **incremental signals** are output as the square-wave pulse trains U_{a1} and U_{a2}, phase-shifted by 90° elec. The **reference mark signal** consists of one or more reference pulses U_{a0}, which are gated with the incremental signals. In addition, the integrated electronics generate the **inverted signals** U_{a1}⁻, U_{a2}⁻, and U_{a0}⁻ for noise-immune transmission. The illustrated sequence of output signals—with U_{a2} lagging U_{a1}—applies to the direction of motion shown in the dimension drawing.

The **fault detection signal** U_{aS}⁻ indicates malfunctions such as supply line breakage, failure of the light source, etc.

The distance between two successive edges of the incremental signals U_{a1} and U_{a2} through 1-fold, 2-fold, or 4-fold evaluation is one **measuring step**.

Further information:

For detailed descriptions of all available interfaces, as well as general electrical information, please refer to the *Interfaces of HEIDENHAIN Encoders* brochure.

A shielded cable with a cross section of at least 0.5 mm² is recommended when connecting the handwheel to the power supply. The handwheel is connected via screw terminals. The wires must be provided with the appropriate ferrules.

HTL, HTLs incremental signals

HEIDENHAIN encoders with the HTL interface contain electronics that digitize sinusoidal scanning signals with or without interpolation.

The **incremental signals** are output as the square-wave pulse trains U_{a1} and U_{a2} , phase-shifted by 90° elec. The **reference mark signal** consists of one or more reference pulses U_{a0} , which are gated with the incremental signals. In addition, the integrated electronics generate the **inverted signals** $\overline{U_{a1}}$, $\overline{U_{a2}}$, and $\overline{U_{a0}}$ for noise-immune transmission (not with HTLs). The illustrated sequence of output signals—with U_{a2} lagging U_{a1} —applies to the direction of motion shown in the dimension drawing.

The **fault detection signal** $\overline{U_{aS}}$ indicates a malfunction such as failure of the light source, etc.

The distance between two successive edges of the incremental signals U_{a1} and U_{a2} through 1-fold, 2-fold, or 4-fold evaluation is one **measuring step**.

Further information:
For detailed descriptions of all available interfaces, as well as general electrical information, please refer to the *Interfaces of HEIDENHAIN Encoders* brochure.

Power and current consumption

For encoders with a wide supply voltage range, the current consumption exhibits a nonlinear relationship to the supply voltage. It is determined using the calculation described in the *Interfaces of HEIDENHAIN Encoders* brochure.

For the rotary encoders with additional HTL output signals, the power consumption also depends on the output frequency and cable length. The power consumption values for the HTL and HTLs interfaces can therefore be read off separately from the diagrams.

The maximum permissible output frequency is shown in the specifications. This frequency occurs at the maximum permissible shaft speed. The output frequency for any shaft speed is calculated using the following formula:

$$f = (n/60) \cdot z \cdot 10^{-3}$$

With
 f = Output frequency in kHz
 n = Shaft speed in rpm
 z = Number of signal periods per 360°

Power consumption (maximum) for the HTL interface and supply voltage $U_P = 30V$

Power consumption (maximum) for the HTLs interface and supply voltage $U_P = 30V$

Cable length for HTL

For those rotary encoders with additional HTL output signals, the maximum permissible cable length may vary depending on several criteria:

- Output frequency
- Supply voltage
- Operating temperature

The diagrams show these relationships separately for the HTL and HTLs interfaces. At a supply voltage of DC 10V, there are no limitations on cable length.

Maximum permissible cable length for the HTL interface

Maximum permissible cable length for the HTLs interface

EnDat position values

For connection, a shielded cable with a cross section of at least 0.5 mm² is recommended for the power supply. The connection is performed via screw terminals. The wires must be provided with the appropriate ferrules.

The EnDat interface is a digital, **bidirectional** interface for encoders. It is capable of outputting **position values**, reading information stored in the encoder, updating this information, and storing new information. Because the interface uses **serial transmission**, only **four signal lines** are required. The data (DATA) are transmitted in **synchronism** with the CLOCK signal from the downstream electronics. The type of transmission (position values, parameters, diagnostics, etc.) is selected via mode commands that the downstream electronics send to the encoder. Some functions are available only with EnDat 2.2 mode commands.

Further information:

For detailed descriptions of all available interfaces, as well as general electrical information, please refer to the *Interfaces of HEIDENHAIN Encoders* brochure.

Integrated temperature evaluation

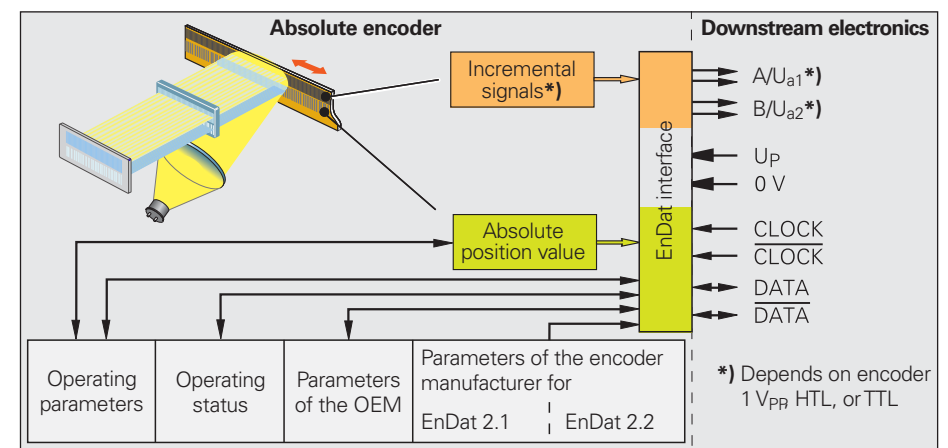

Rotary encoders with EnDat 2.2 feature an internal temperature sensor integrated into the encoder electronics. The digitized temperature value is transmitted purely serially via the EnDat protocol. Please bear in mind that this temperature measurement and transmission is not safe in terms of functional safety.

With regard to the internal temperature sensor, these rotary encoders support the two-stage cascaded signaling of a temperature exceedance. This signaling consists of an EnDat warning and an EnDat error message.

In compliance with the EnDat specification, when the temperature reaches the warning threshold for the temperature exceedance of the internal temperature sensor, an EnDat warning is issued (EnDat memory area "Operating status," word 1 "Warnings," bit 2¹ "Temperature exceeded").

Ordering designation	Command set	Incremental signals
EnDat01 EnDatH EnDatT	EnDat 2.1 or EnDat 2.2	1 V _{PP} HTL TTL
EnDat21		—
EnDat02	EnDat 2.2	1 V _{PP}
EnDat22	EnDat 2.2	—

Versions of the EnDat interface

This warning threshold for the internal temperature sensor is stored in the EnDat memory area "Operating parameters," word 6 "Trigger threshold warning bit for excessive temperature," and can be individually adjusted. A device-specific default value is saved here before shipping. The temperature measured by the internal temperature sensor is higher by a device-specific and application-specific amount than the temperature at measuring point M1 in accordance with the dimension drawing.

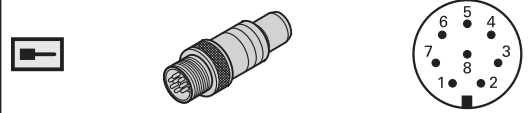

The encoders feature a further, albeit non-adjustable, trigger threshold of the internal temperature sensor, which, when exceeded, triggers an EnDat error message (the EnDat memory area "Operating status," word 0 "Error messages," bit 2² "Position," and in additional data 2 "Operating status error sources," bit 2⁶ "Temperature exceeded"). This threshold may vary depending on the encoder and is stated in the specifications.

HEIDENHAIN recommends adjusting the warning threshold based on the application such that this threshold is sufficiently below the trigger threshold for the "Temperature exceeded" EnDat error message. Compliance with the operating temperature at measuring point M1 is required for adherence to the encoder's proper and intended use.

Siemens pin layout

Siemens pin layout

HEIDENHAIN encoders with the code letter S after the model designation are suitable for connection to Siemens controls with the **DRIVE-CLiQ interface**

- Ordering designation: DQ01

RJ45 connector	Power supply		Serial data transmission			
	A	B	Transmit data		Receive data	
	1	5	3	6	1	2
	1	5	7	6	3	4
	U _P	0V	TXP	TXN	RXP	RXN

Cable shield connected to housing; U_P = Power supply voltage

Integrated temperature evaluation

Rotary encoders with the DRIVE-CLiQ interface include an internal temperature sensor integrated into the encoder electronics. The digitized temperature value is transmitted purely serially via the DRIVE-CLiQ interface. Please bear in mind that neither the temperature measurement nor the transmission of the temperature value is safe in terms of functional safety.

The temperature measured by the internal temperature sensor is higher by a device-specific and application-specific amount than the temperature at measuring point M1 in accordance with the dimension drawing.

Upon reaching a trigger threshold for the internal temperature sensor, these rotary encoders issue an "Alarm 405" error message. This threshold may vary

depending on the encoder and is stated in the specifications. During operation, HEIDENHAIN recommends keeping the temperature adequately below the trigger threshold for the error message.

Compliance with the operating temperature at measuring point M1 is required for adherence to the encoder's proper and intended use.

SSI position values

The **position value** is transmitted, starting with the most significant bit (MSB), over the data lines (DATA) in synchronism with a clock signal (CLOCK) provided by the control. The SSI standard data word length for singleturn encoders is 13 bits, and for multiturn encoders, 25 bits. In addition to the absolute position values, **incremental signals** can be transmitted as well. For a signal description, see 1 V_{PP} incremental signals.

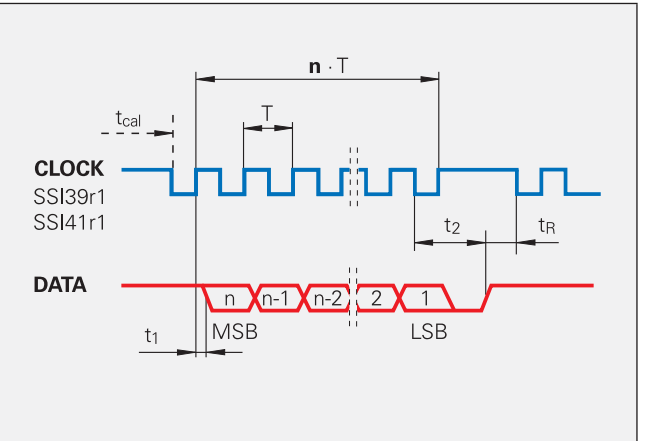

The following **functions** can be activated via programming inputs:

- Direction of rotation**
- Zero reset** (setting to zero)

Data transmission

T = 1 to 10 μs
 t_{cal} See Specifications
 t₁ ≤ 0.4 μs (without cable)
 t₂ = 17 μs to 20 μs
 t_R ≥ 5 μs
 n = Data word length
 13 bits for ECN/ROC
 25 bits for EQN/ROQ

CLOCK and DATA not shown

With 8-pin M12 connector (female) and 8-pin M12 coupling (male)		Ø 6.8 mm	822504-xx
With 8-pin M12 connector (female) and RJ45 Siemens connector (IP67); cable length: 1 m		Ø 6.8 mm	1094652-01
With 8-pin M12 connector (female) and RJ45 Siemens connector (IP20)		Ø 6.8 mm	1093042-xx

A_P : Cross section of power supply lines

Signal converters

Signal converters from HEIDENHAIN adapt the encoder signals to the interface of the downstream electronics. They are used when the downstream electronics cannot directly process the output signals from HEIDENHAIN encoders or when additional interpolation of the signals is necessary.

Input signals of the signal converters

HEIDENHAIN signal converters can be connected to encoders that output 1 V_{PP} sinusoidal signals (voltage signals) or 11 μA_{PP} sinusoidal signals (current signals). Encoders with the EnDat or SSI serial interfaces can be connected to various signal converters as well.

Output signals of the signal converters

The signal converters are available with the following interfaces to the downstream electronics:

- TTL square-wave pulse trains
- EnDat 2.2
- DRIVE-CLiQ
- Fanuc Serial Interface
- Mitsubishi high speed interface
- Yaskawa Serial Interface
- PROFIBUS

Interpolation of the sinusoidal input signals

The signal converters perform signal conversion and interpolate the sinusoidal encoder signals. This permits finer measuring steps, resulting in higher control quality and superior positioning behavior.

Generation of a position value

Various signal converters feature an integrated counting function. Starting from the last set reference point, an absolute position value is generated and output to the downstream electronics when the reference mark is traversed.

Plug design

¹⁾ Switchable

Testing and inspection devices, and diagnostics

HEIDENHAIN encoders provide all of the information necessary for initial setup, monitoring, and diagnostics. The type of information available depends on whether the encoder is incremental or absolute and on which interface is being used.

Incremental encoders primarily have 1 V_{PP} TTL, or HTL interfaces. TTL and HTL encoders monitor their signal amplitudes internally and generate a purely digital fault detection signal. With 1 V_{PP} signals, an analysis of the output signals is possible only with external testing devices or through the use of computation resources in the downstream electronics (**analog diagnostics interface**).

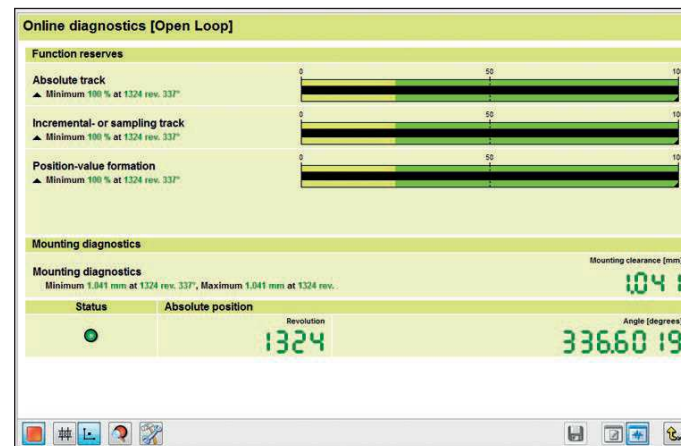

Absolute encoders employ serial data transmission. Depending on the interface, additional 1 V_{PP} incremental signals can be output. The signals are extensively monitored within the encoder. The monitoring results (specifically, valuation numbers) can be transmitted to the downstream electronics along with the position values via the serial interface (**digital diagnostics interface**).

- The following information is available:
- Error message: position value is not reliable
 - Warning: an internal functional limit of the encoder has been reached
 - Valuation numbers:
 - Detailed information about the encoder's functional reserve
 - Identical scaling for all HEIDENHAIN encoders
 - Cyclic reading is possible

This enables the downstream electronics to evaluate the current status of the encoder with little effort, even in closed loop mode

For the analysis of these encoders, HEIDENHAIN offers the appropriate PWM inspection devices and PWT testing devices. Depending on how these devices are integrated, a distinction is made between two types of diagnostics:

- Encoder diagnostics: the encoder is connected directly to the testing or inspection device, thereby enabling a detailed analysis of encoder functions.
- Monitoring mode: the PWM inspection device is linked into the closed control loop (via suitable testing adapters if needed). This enables real-time diagnosis of the machine or equipment during operation. The available functions depend on the interface.

Diagnostics with the PWM 21 and ATS software

Commissioning with the PWM 21 and ATS software

Overview		PWM 21		PWT 101
Interface	Output signals	Encoder diagnostics	Monitoring mode	Encoder diagnostics
EnDat 2.1	Position value Incremental signals	Yes Yes	No Yes	Yes Yes

Commutation	Block commutation Sinusoidal commutation	Yes ²⁾ Yes	No Yes	Yes ³⁾ Yes

¹⁾ Information must be requested and transferred by the control

²⁾ Via the appropriate signal adapter

³⁾ Only for encoders with block commutation (see encoder documentation)

⁴⁾ If supported by the encoder (PWT function)

⁵⁾ Not available for encoders with the ordering designation Mitsu01

⁶⁾ Not available for the EIB 3391Y

⁷⁾ Function not available yet

⁸⁾ Two-pair transmission is required (for more information, see the documentation for the PWT 100/PWT 101)

PWT 101

The PWT 101 is a testing device for the functional testing and adjustment of incremental and absolute HEIDENHAIN encoders. Thanks to its compact dimensions and rugged design, the PWT 101 is ideal for portable use.
